FOREWORD

In 1956, the State Legislature declared "that in providing for the full development and utilization of the water resources of this State it is necessary to obtain for consideration by the Legislature and the people, information as to the water which can be made available for exproation from the watersheds in which it originates without depriving those watersheds of water necessary for beneficial uses therein." The Department of Water Resources was therefore authorized and directed to conduct such investigations as necessary to compile this information. To do so, the department began its statewide Inventory of Water Resources and Water Requirements as outlined in the authorizing legislation (Water Code Section 232).

For purposes of this inventory, the State has been divided into major hydrographic areas. These areas, in turn, have been subdivided into hydrographic units generally comprising watersheds of individual rivers. Basic data, consisting of land and water use, classification of lands, and streamflow measurements, are collected for each hydrographic unit. To date, this activity has been concentrated mainly in northern watersheds. Results of this inventory will be presented in two series of reports covering (1) land and water use, and (2) water resources and water requirements.

The data on land and water use, together with land classification, are being published as the Bulletin 94 series; one for each hydrographic unit. This report covering the Shasta-Scott Valleys Hydrographic Unit is the fifth in the series. As the data relative to particular hydrographic units are published they become available for general studies and project investigations, not only by the department, but by all parties concerned with the watersheds covered. When completed, this series of bulletins will provide detailed data for the whole State.

A second series of reports, each covering one or more hydrographic units, will include determinations of the available water resources and future requirements of those areas. The water resources will be determined from the records of older stream gaging stations, and a number of new stations, mainly on smaller streams not previously measured. The determination of future water requirements will be based on land use patterns projected for specific points of time. These projections, in turn, will be based on the land and water use and land classification data, such as contained herein, and other available information.

Although the data developed by this inventory are to be used throughout the department's planning activities, they are most urgently needed for the staging of water projects. For this reason, the development of these data and their application to the timing of projects were combined in the Water Requirements and Project Staging Program in 1961. Under this program, determinations of the quantities of water available and of the time, place, and magnitude of the future water needs of the entire State, are being combined in the formulation of a sequence of projects to meet those needs. An interim staging report will be published in 1963-64.

THE RESOURCES AGENCY OF CALIFORNIA
DEPARTMENT OF WATER RESOURCES

1120 N STREET, SACRAMENTO

April 10, 1963

Honorable Edmund G. Brown, Governor, and
Members of the Legislature of the
State of California

Gentlemen:

Transmitted herewith is a preliminary report prepared by the Department of Water Resources entitled, "Land and Water Use in Shasta-Scott Valleys Hydrographic Unit," Bulletin No. 94-5. This is the fifth of a series of reports of the Department of Water Resources which presents detailed basic data relative to land and water use within certain hydrographic units of the State and is the outcome of a study made under the authority granted in Section 232 of the Water Code. This series, when completed, will form an invaluable reference of the total water resources of the State in their relation to certain classes and uses of land resources.

The data presented herein will provide a factual basis for decisions of interested parties concerning matters related to land and water use in the area of investigation. In addition to the detailed material on land and water use, the report includes notes on the history, natural features, climate, and economy of Shasta-Scott Valleys Hydrographic Unit. Maps of land use and land classification illustrate the text.

The information contained in this series of reports will provide a basis for future estimates of the amount of water which originates within each watershed, the amount which can be used beneficially within each area, and the extent of surplus or deficiency, if any.

All public and private agencies, local interests, and individuals who may be concerned with the information presented herein are invited to submit their comments. A public hearing will be held after due notice to consider all comments prior to preparation of the final report.

Sincerely yours,

A handwritten signature in dark ink, appearing to read "Hugo Fisher".

ACKNOWLEDGMENT

The Department of Water Resources gratefully acknowledges information contributed by the numerous water users and residents of the Shasta-Scott Valleys Hydrographic Unit and various agencies of the federal, state, and local governments.

Special mention is made of the helpful cooperation of the Siskiyou County Farm Bureau for its assistance in arranging and conducting reviews of information published herein.

CHAPTER I. INTRODUCTION

This bulletin presents basic data on land and water use in portions of Shasta River and Scott River watersheds. These areas, located in Siskiyou County, are designated herein as the Shasta-Scott Valleys Hydrographic Unit. The data cover present land and water use, classification of lands, systems used to divert surface waters, histories of diversions, apparent water rights pertinent to each diversion, purpose and extent of use of diversions, seasonal quantities of water diverted during 1958, and an estimate of present consumptive use of water in the unit. A general description and a brief history of the area are also included.

These basic data were gathered during the period 1958-59 in compliance with Chapter 61, Statutes of 1956, as amended by Chapter 2025, Statutes of 1959, and codified in Section 232 of the Water Code of the State of California. This legislation provides for an inventory of water resources and water requirements of the State. This is the fifth of a series of bulletins to be prepared under this authorization. The text of Section 232, with a discussion of its history and implications, is included in this bulletin as Appendix A.

These data will provide the basis for a future determination of the quantities of water reasonably required for future beneficial use within the Shasta-Scott Valleys Hydrographic Unit. Preliminary estimates of these quantities were published in State Water Resources Board Bulletin No. 2, "Water Utilization and Requirements of California," Department of Water Resources Bulletins No. 58, "Northeastern Counties Investigation," and No. 83, "Klamath River Basin Investigation."

Final determinations of future water requirements will be based on estimates of: (1) future land use, (2) economic considerations, (3) population, (4) industrial and agricultural development, and (5) recreational needs.

The data presented herein have been reviewed in preliminary form by representatives of Siskiyou County, the Water Study Committee of the Siskiyou County Farm Bureau, and local water users. These groups submitted changes, which were reviewed in the field, and adjustments were made where warranted.

Organization of Report

This bulletin is basically a compilation of data in the form of tables and plates, with supplemental explanatory text. The report consists of five chapters, four appendixes, and three plates.

Chapter I contains a general description and brief history of the Shasta-Scott Valleys Hydrographic Unit. Chapter II, "Water Use," presents data on surface water diversion systems, related water rights information, measurements of quantities of water diverted, and an analysis of consumptive use. Chapter III, "Land Use," includes a history of land use within the unit, and tables of present land use. Plates prepared in connection with Chapters II and III delineate the areas of various present land uses and the locations of diversion systems. Chapter IV, "Land Classification," includes a tabulation of lands classified with regard to their potential for irrigated agriculture and for recreational purposes. Plates prepared for this chapter delineate the respective classes of land grouped into several major categories. Chapter V summarizes the report.

Appendix A presents the text of Section 232 of the California Water Code and a discussion of the pertinent responsibilities and work program of the Department of Water Resources. Appendix B is a bibliography of publications pertinent to the Shasta-Scott Valleys Hydrographic Unit. Appendix C presents a short summary of California water law, a review of litigation involving water rights in the unit, and a tabulation of applications to appropriate water in the unit. Appendix D presents details of six diversions which could not be adequately described in tables contained in Chapter II.

General Description of Area

Location

The Shasta-Scott Valleys Hydrographic Unit, which contains 1,456 square miles of central Siskiyou County, lies within the Klamath River Basin of the North Coastal area as shown on Plate 1. The unit includes the entire watershed of the Shasta River and that portion of the Scott River watershed which is above the gaging station "Scott River near Fort Jones," located 20 miles above the confluence of the Scott and Klamath Rivers. The unit is bounded by the watersheds of the Klamath River on the north, the Salmon River on the west, the Trinity and Sacramento Rivers on the south, and Butte Creek on the east.

The Shasta River heads in the Eddy Mountains and flows northerly for approximately 50 miles through Shasta Valley to its junction with the Klamath River. Major tributaries are Little Shasta River, Greenhorn Creek, Yreka Creek, Willow Creek, Parks Creek, Boles Creek, Beaughan Creek, and Carrick Creek.

The headwaters of the East Fork Scott River rise on China Mountain about 7 miles southeast of Callahan. The headwaters of the South Fork Scott River are the mountain lakes about 5 miles southwest of Callahan. These two forks merge at Callahan to form the Scott River, which flows northerly for approximately 30 miles along the east side of Scott Valley to Fort Jones, then westerly for 10 miles, where it leaves the valley and the hydrographic unit. Major tributaries to the Scott River are Shackelford Creek, French Creek, Etna Creek, Kidder Creek, McAdams Creek, and Moffett Creek.

For purposes of this report, the Shasta-Scott Valleys Hydrographic Unit has been divided into 20 subunits, shown on Plate 1. The area of each subunit is shown in Table 1.

Historical and Present Development

Like most of the American continent prior to the white man's arrival, Shasta and Scott Valleys were inhabited by Indians -- the Shastas in Shasta Valley, and the Ottitiewa Tribe in Scott Valley. The first known white man to enter the area was Gene Baptiste McKay, who camped near Sheep Rock on the eastern side of Shasta Valley in 1825. Peter Skene Ogden made the first recorded mention of Mt. Shasta on February 14, 1827. He called it Mt. Sastise, and the river Sastise River.

A party of Hudson's Bay Company trappers, under the guidance of Alexander Roderick McLeod, came down the Oregon Coast in 1827 and passed through Scott Valley on their way to the Sacramento Valley. They called it Beaver Valley, due to the large number of beaver inhabiting the area.

TABLE 1
AREA OF SUBUNITS IN
SHASTA-SCOTT VALLEYS HYDROGRAPHIC UNIT

Subunit	: Acres	: Square miles
Ball Mountain	30,960	48

Stewart Springs	18,100	28
Weed	32,590	51
Willow Creek	49,260	77
Yreka Creek	39,030	61
TOTAL AREA	931,900	1,456

Several trapping and exploring expeditions passed through the two valleys, but the area remained almost unknown until the discovery of gold at Coloma. Major Reading's discovery of gold on the Trinity River led to the search for the precious metal on other northern streams. Would-be miners came from the Sacramento Valley, from the Pacific Coast up the Klamath River, and south through the mountains from Oregon.

In March of 1851, a party of miners led by Dr. F. G. Hearn, passing over the Siskiyou Mountains from Oregon to Scott Bar, was delayed at Ieka (Yreka) Creek after a three-day rainstorm. During the delay, Abraham Thompson noticed flecks of gold in the

roots of grass that were turned by the stock and washed by the rain. Upon panning, he found the topsoil to be extremely rich. The area became known as "Thompson's Dry Diggings," and within six months after Thompson took out the first gold, 5,000 people inhabited the area. Stores, saloons, and gambling houses became part of the settlement known as Shasta-Butte City. This name was later changed to Yreka when Siskiyou County was formed in 1852. As was found to be the experience in other gold mining areas, a decline in population followed the disappearance of the more readily accessible deposits. Population in Yreka, presently the largest town in the unit, dropped to about 1,000 people in 1870, and remained under 1,300 until about 1920. Since that time, the population increased to 2,500 in 1940, and 4,800 in 1960.

Weed, the second largest town in the unit, was established in 1900, when a large sawmill and lumber products manufacturing plant were constructed. Although some of the town's growth between 1900 and 1960 can be attributed to tourist trade passing through on U. S. Highways 99 and 97, the major changes in Weed's economic activity can be traced to changes in the output level of lumber products. Since World War II, this lumber mill has become a part of the largest forest products firm in the United States, the International Paper Company. During the past 15 years, a plywood plant and other manufacturing facilities have been added. Population has consequently increased from about 2,700 in 1950 to 3,200 in 1960.

Montague, the third largest town, is located 6 miles east of Yreka, in a dairying and stock raising community. The

surrounding farmland was developed prior to 1920 by a local land company, and agriculture of the area has not expanded greatly since that time. The population of Montague has increased slowly from 250 in 1890 to 500 in 1930, and to about 800 in 1960.

Edgewood, Gazelle, and Granada are small, unincorporated towns on the stage line of the old California-Oregon Trail.

The town of Etna was originally known as Rough and Ready Mills, for the flour mills established there in 1856. The town originally served as a supply center for the southern Siskiyou gold mining area. After the gold rush, Scott Valley developed into an agricultural area, and Etna became the agricultural center for the southern portion of the valley. Population of the town has fluctuated from about 360 in 1880, to 500 in 1900, to 380 in 1930, and about 600 in 1960.

Fort Jones, known variously as Ottitiewa, Wheelock, and Scottsburg, was established in 1851 as a hotel and stage station on the road from Yreka to Callahan. In 1862 the present name of Fort Jones was adopted from an army post 1 mile to the south, which had existed from 1852 to 1858 for protection against the Indians. Population has increased slowly from 250 in 1890 to about 500 in 1960.

At the junction of East and South Forks Scott River, a wayside inn was founded in 1851 for miners crossing the Scott Mountains from the south. This was the first stage station to be built in Siskiyou County. In 1854 the Callahan Ranch Hotel was built. The building is still in use today, containing the post office and general store. Although no precise estimate of the

Town of Yreka

City of Weed -- International Paper Company

population of the town proper has been made, school attendance indicates that Callahan has less than 100 residents.

During the 1850's, the community of Deadwood, then second in size only to Yreka, was formed at the junction of Deadwood and Cherry Creeks, 8 miles west of Yreka. This was a rich gold area and was mined extensively until 1900. Very little remains today to indicate that a prosperous mining community once occupied the site.

The Shasta-Scott Valleys Hydrographic Unit contains approximately 568,000 acres of commercial timberland, with a volume of about 8.8 billion board feet. About 70 percent of this acreage is in private ownership, the remainder being in either national forest, Indian lands, or public domain. Coniferous timber in the area is composed of three principal types: pine, Douglas fir, and true firs.

In 1958, two sawmills were operating in Scott Valley, with a combined capacity of 40 million board feet per year. In Shasta Valley, there were four sawmills with a total capacity of about 100 million board feet per year, a plywood plant with an output of 360 million square feet, and a lumber remanufacturing plant with a capacity of 30 million board feet per year.

Agriculture ranks next to lumbering in Siskiyou County's economy. About one-half of the county's total agricultural production comes from Shasta and Scott Valleys. Beef cattle production is the principal source of agricultural income in the hydrographic unit, followed in importance by hay and grain crops.

Gold mining, which was the initial stimulus to settling of the area in 1850, has continued to be an important element in

Shasta River Dam, Dwinnell Reservoir

Town of Montague

the unit's economy. Although production dropped off during World War II, it amounted to approximately \$460,000 during 1955, and \$260,000 during 1958. Sand and gravel output during 1958 was valued at about \$230,000; miscellaneous stone at about \$110,000; and the production of chromite was about \$30,000.

Natural Features

The Shasta-Scott Valleys Hydrographic Unit consists of the two valleys and surrounding mountains. Shasta Valley, which has a north-south length of about 30 miles, and a maximum width of 15 miles, has an area of about 220 square miles. The valley varies in elevation from about 2,500 feet above sea level near Montague to about 3,000 feet near Edgewood. It is situated along the eastern slopes of the Klamath Mountains and includes a portion of the western slopes of the Cascade Range.

In the west-central portion of Shasta Valley, rocks typical of the Klamath Mountains geomorphic province give way eastward to the Tertiary and Quaternary volcanic rocks of the Cascade Range. The valley may be divided into four areas having distinct geologic and topographic characteristics. These are: (1) a discontinuous, gently eastward-sloping alluvial plain along the western portion of the valley; (2) an area of volcanic hillocks, ridges, and alluvial flats in the western and central parts of the valley; (3) a large, gently sloping recent basaltic lava flow, which covers most of the southeast quarter of the valley; and (4) dissected, gently sloping coalescing alluvial fans at the north end of the valley. The Cascade Range bordering the east

side of Shasta Valley consists of a north-south trending chain of dormant or extinct volcanoes. Mount Shasta, the highest volcanic cone in the chain, rises almost 2 miles above its base to 14,162 feet above sea level at the southeast end of Shasta Valley, to dominate the surrounding landscape.

Scott Valley, which has a north-south length of about 20 miles, is narrow at its southern section near Callahan, and widens to about 7 miles near Greenvew. The area of the valley is approximately 100 square miles and, like Shasta Valley, varies in elevation from about 2,500 feet to 3,000 feet above sea level. Southeast of the valley are the Scott Mountains; to the west and south are the Salmon Mountains; and to the north and northwest are the Scott Bar and Marble Mountains. Formations surrounding and underlying the valley fill consist of bedrock of pre-Silurian to Jurassic and possibly Cretaceous age. The alluvial fill consists of unconsolidated Pleistocene and Recent deposits.

Soils of the Shasta and Scott Valleys differ markedly as to their mode of formation, physiographic configuration, age, and parent rock material. These differences are significant when considering the respective crop adaptabilities of the two valleys. The soils can be arranged into four groups: (1) recent and young alluvial soils; (2) morainic soils; (3) older valley-filling soils; and (4) upland or residual soils. All of these types are found in Shasta Valley, but Scott Valley is comprised largely of alluvial soils.

The soils of Shasta Valley have been severely modified by volcanic activity in the Mt. Shasta region. Many ridges and

Lower Scott Valley, Fort Jones

Town of Etna

mounds of extruded volcanic rocks have broken the valley into numerous small and sometimes isolated pockets of irrigable soils. Glacial action has left an extensive area of coarse-textured, stony morainic soils in the southern end of the valley. Some limited areas of alkali are scattered throughout the valley. However, analysis of soil samples has indicated that the alkali problem is not serious. The older valley-filling soils of Shasta Valley are shallow, with undulating hardpan below.

Crop adaptability of the land of Shasta Valley is limited by the presence of rock, coarse-textured materials, and root-restricting hardpans. Further restrictions are imposed by spring flooding and short growing seasons. Crops such as pasture, alfalfa, small grains, and selected field crops, will probably continue to be the major crops grown in the valley.

Crop adaptability in Scott Valley has the same general limitations as Shasta Valley. A major portion of the soils of Scott Valley are recent and young alluvium from mixed or sedimentary parent rock sources. The western edge of the valley has several areas of coarse and stony soils. Many of the soils found adjacent to existing water courses are subject to a high water table in the early spring. At present, the valley produces alfalfa, grain, meadow pasture, and a limited selection of field crops. Over-irrigation has greatly reduced the carrying capacity of much of the meadow pasture land. Crop adaptability of most of this area is more limited by climatic environment than by soil restrictions. In the future, Scott Valley is likely to shift toward greater field crop production and a more intensive management of pasture lands.

Climate

The climate of the Shasta-Scott Valleys Hydrographic Unit is characterized by warm dry summers and moderate wet winters. In the valleys, the average maximum temperature for July, the hottest month, is approximately 92°F. The average minimum for January, the coldest month, is about 23°F. In higher elevations of the mountains, the temperature decreases about one degree per 300 feet of elevation. The mean and extreme temperatures, and the average frost-free period, for four representative stations, are shown in Table 2.

TABLE 2
SUMMARY OF RECORDED
TEMPERATURES AT SELECTED STATIONS IN
OR NEAR SHASTA-SCOTT VALLEYS
HYDROGRAPHIC UNIT

Water Resources

The flow in the Shasta and Scott Rivers is extended into the summer, beyond the main precipitation period, by the melting snowpack of the Eddys, the Scott Mountains, and the Salmon Mountains. Boles Creek, Beaughan Creek, Carrick Creek, Big Springs, and other small streams and springs in Shasta Valley are supplied by underground flow from the melting glaciers of Mt. Shasta.

Runoff from the hydrographic unit is measured at the gaging stations designated as Shasta River near Yreka, and Scott River near Fort Jones. Pertinent information obtained from these stations for the period indicated is summarized in Table 4.

TABLE 4

SUMMARY OF RUNOFF DATA FOR
SHASTA RIVER NEAR YREKA AND
SCOTT RIVER NEAR FORT JONES

Item of record	Shasta River		Scott River	
	Acre-feet	Period	Acre-feet	Period

CHAPTER II. WATER USE

Water requirements in the Shasta-Scott Valleys Hydrographic Unit are met almost entirely by diversion of stream runoff; however, a limited portion is supplied by ground water. A survey of surface water diversions was made for this investigation. The results of the survey include diversion locations, descriptions, uses, amounts of water diverted, and apparent water rights information relating to diversions. Diversions of water for all purposes are reported, except those which involve amounts less than approximately 10 acre-feet per season.

Quantities of water diverted during 1958 were measured in order to further describe the diversion systems. The measured quantities do not necessarily represent average diversions, since in any single year the quantity diverted will be influenced by precipitation during the growing season and the available streamflow. As was mentioned in Chapter I, 1958 was an unusually wet year in Shasta and Scott Valleys. Factors other than available water supply, such as economic factors, may also affect the degree to which any diversion record represents typical operating conditions. No attempt was made to assess these factors in this report. Generally, the diversion quantities reported are the actual amounts of water taken from the respective sources, and therefore include the recoverable and irrecoverable losses incidental to the primary uses, which may be consumptive, such as irrigation, or nonconsumptive, such as in the production of hydroelectric power.

Locating water wells and measurement of their production were not covered in this investigation. However, the areas of lands irrigated by water from all sources, including underground sources, were determined in the land use survey, which is described in Chapter III.

Urban water service in the unit is provided in the following localities:

<u>Location</u>	<u>Owner</u>	<u>Source</u>
Etna	City of Etna	Etna Creek
Fort Jones	Dunsmuir Water Corporation	Wells
Montague	City of Montague	Little Shasta River
Weed	International Paper Company	Beaughan Creek
Weed	Shastina Water Service	Boles Creek
Yreka	City of Yreka	Greenhorn Creek Yreka Creek

Water Rights

Water rights are an important consideration when determining the quantities of water which are surplus to the present and future needs of an area. Therefore, information relative to the apparent water rights associated with the surface water diversions described herein was obtained. These rights are based on appropriative or riparian status, and may have been defined by adjudication.

Water rights are rights in property which, because of their obscure establishment, are frequently the subject of controversy and litigation. Most of the water rights in Shasta Valley,

1
ids
1,

er

Lumber Mill, Weed

Big Springs, Shasta Valley

and some of the water rights in Scott Valley, have been adjudicated. Others have been defined in private agreements. These actions, and the California law of water rights, are described briefly in Appendix C.

Most of the remaining water use in the unit is based on riparian rights, or on appropriative rights established prior to 1914. As of June 28, 1960, a total of 68 currently active applications had been made in the unit under provisions of the Water Commission Act of 1914. Permits or licenses had been granted for 66 of these applications, and 2 were incomplete. All of these applications are tabulated in Table C-1.

Surface Water Diversions

During the survey, an attempt was made to locate and obtain data with respect to all diversions of more than 10 acre-feet per year. All diversions actually in use in 1958, as well as those which had been used within the preceding five years, were included. The date of last use of discontinued diversions was recorded, if known. Direct diversions, as well as those involving significant surface storage, were located. All reservoirs which had surface areas of about 3 acres or more were mapped. Three acres was considered the minimum area which could be delineated with reasonable accuracy on the aerial photographs used. Reservoirs located along, and operated in conjunction with, canals and ditches are shown on the land and water use maps, but are not considered as separate systems, and are not assigned location numbers. Similarly, supplies obtained from small, intermittent streams intercepted by canal systems are not classed as separate diversions.

d. In some situations, water users have made efficient use
d of water by rediverting field runoff or spill collected from their own upstream diversion systems. In this investigation, the point of such rediversion is neither located on the maps nor assigned a number. If return flow from another water user's operation is rediverted, however, or if there is doubt as to the origin of the water, the diversion is delineated and assigned a number. Diversion systems of water companies or groups of water users are considered as single units; individual customer distribution points are not shown on the maps.

A total of 541 surface water diversions were located in this unit in 1958, and are classified by primary use as follows:

<u>Primary use</u>	<u>Number of diversions</u>
Irrigation	524
Municipal	11
Industrial (lumber mills)	3
Power	2
Recreation (golf course)	1

e Points of diversion and main canals or pipelines used to convey the water are delineated on the 18 sheets of Plate 2, "Land and Water Use." The diversions are described in Table 5.

Numbering System for Surface Water Diversions

Surface water diversions are numbered by a system which indicates their location by township, range, and section within the federal land survey system. Each section is subdivided into 40-acre plots, lettered as shown in the legend on each sheet of

Plate 2. Diversions are numbered within each of these 40-acre plots according to the order in which they were located. For example, diversion 41N/5W-4F1, which is shown on Sheet 15 of Plate 2 as "4F1," is the first diversion located in the SE $\frac{1}{4}$ of the NW $\frac{1}{4}$ of Section 4 in Township 41 North, Range 5 West, Mt. Diablo Base and Meridian (MDB&M).

Descriptions of Surface Water Diversions

Description, history, and other information relating to surface water diversions were obtained by field inspection, by interview with water users or their representatives, and by reference to prior reports and official records. This information is contained in Table 5. Data in the table are arranged by diversion number within each subunit.

Each diversion location in Table 5 is followed by the name of the owner, the source of water, the purposes of each diversion, the quantity of water diverted during 1958, the extent of use, and the method of water application. If the purpose listed is not the usual use for that diversion, notation is made in the remarks column. The extent of domestic use is specified only when five or more connections are served. Stockwatering of less than 10 head of livestock is considered to be a domestic use. The extent of irrigation use is based on the land use survey described in Chapter III.

The type of water right under which the respective diversions are considered to be made is indicated in Table 5 as the "apparent water right." The determination of this item is based upon the best information available from the owner, from files of the State Water Rights Board, from court decrees, from official records

and from other sources. The actual amount of the right, if established and known, and a reference to the source of data, are also included. Although this information is believed to be accurate, it is emphasized that it is not based on sworn claims or testimony, and should in no way be construed to represent a conclusive determination of water rights.

Diversions for which water rights have been adjudicated are listed in Table 5 as "adjudicated." Those based on appropriative rights are listed as "appropriative." Those which have been neither adjudicated nor based on appropriations, but for which the area of use is apparently riparian to the stream or other water source, are listed as "riparian." The areas of use for many of the diversions listed as adjudicated or appropriative are probably riparian to water sources, but no attempt was made to make such determinations.

In the case of an adjudicated right, the amount of the decreed right is tabulated. For an appropriative right, the amount tabulated is that found in the filing, if any, in the application, or in the latest permit or license which may have been issued. The reference given for an appropriation initiated after the effective date of the Water Commission Act (1914) is the number of the application on file with the State Water Rights Board. For appropriations prior to 1914, the reference, if known, is the book and page number of the official county record in which the filing is recorded. Such filings were made in accordance with Sections 1410 and 1422 of the Civil Code as enacted in 1872, which preserved

Pump Diversion -- Big Springs, Shasta Valley

Gravity Diversion, Scott Valley Irrigation District

the priority of a diligent appropriator from the time of filing, and enabled him to prevail over a concurrent nonstatutory appropriator.

A detailed description of the diversion systems, including dams, pumps, and main conduits, as well as any special features, is included in Table 5. The diversions are also classified as gravity, pump, or storage, according to the following descriptions:

Gravity diversion - A system in which water is taken from its natural course at a diversion structure and conveyed by gravity through a canal or pipeline to the area of use. Such a diversion may have a reservoir on the stream but the capacity is small compared with the amount of water diverted, and provides no significant carryover storage from winter to summer.

Pump diversion - A system in which water is pumped from its natural course through a pipeline to the area of use or to a gravity conduit located at a higher elevation.

Storage diversion - A system consisting of or including a surface reservoir having significant carryover storage within each season or from season to season.

Systems which do not conform exclusively to one of these basic types are listed as combinations of those types which best describe them.

The remarks contain such information as the names of former owners, known changes of ownership since 1958, and further details explaining entries in the other columns.

Detailed information with respect to diversions, which could not be presented adequately in Table 5, is included in Appendix C.

Records of Surface Water Diversions

Periodic or continuous measurements of surface water diversions were made during 1958, wherever it was feasible, to

 SHASTA-SCOTT VALLEYS HYDROGRAPHIC UNIT

Diversion Location and Plate 2 sheet number	Diversion name and/or owner	Source	Water use in 1958			Apparent water right			Indicated date of appropriation or first use	Description of diversion system	Remarks
			Purpose	Extent and method of use	Amount diverted in acre-feet	Type	Amount	Reference			
GRASS LAKE SUBUNIT											
No diversions located in this subunit											
BRENADA SUBUNIT											
42N/6W-2P1 (Sheet 11)	Edson L. Foulke	Kiernan Slough	Irrig. Stock.	109 acres by flooding* 120 head	230*	Riparian	--	--	Prior 1958	Gravity; earth dam 6 feet high, 20 feet long with 0.5 mile of earth ditch.	Previously irrigated an additional 4 acres. Area irrigated received supplemental supply from 41N/5W-9P1 (Weed Subunit). Amount diverted irrigated an additional 6 acres jointly with 42N/6W-2P2.
42N/6W-2P2 (Sheet 11)	Edson L. Foulke	Kiernan Slough	Irrig. Stock.	20 acres by flooding* 30 head	719*	Adjud.	0.60 cfs ^h 0.25 cfs ^j	Par. 121 ^g	1856	Gravity; earth dam 5 feet high, 15 feet long with 1.0 mile of earth ditch.	Former owner: Edson and Foulke Company. Amount diverted irrigated an additional 6 acres jointly with 42N/6W-2P1.
42N/6W-3H1 (Sheet 11)	Edson L. Foulke	Willow Creek	Irrig.	698 acres by flooding*	1,310	Adjud.	(**)	(**)	About 1854	Gravity; 0.7 mile of earth ditch.	Former owner: Edson and Foulke Company. Area irrigated received supplemental supply from 41N/5W-9P1 (Weed Subunit).
42N/6W-3R1 (Sheet 11)	Fred Carpenter	Willow Creek	Irrig.	38 acres by sprinkler	50	Riparian	--	--	Prior 1958	Pump; electric motor with a short pipeline.	
42N/6W-9P1 (Sheet 11)	Dan Shelley	Willow Creek	Irrig.	16 acres by flooding	Not meas.	Adjud.	0.10 cfs ^h	Par. 307 ^g	1890	Gravity; 200 feet of earth ditch.	Former owners: L. Wortman, Nelson W. Chisholm.
42N/6W-9Q1 (Sheet 11)	Dan Shelley	Willow Creek	Irrig.	213 acres by flooding*	80*	Adjud.	0.25 cfs ^h	Par. 41 ^g	1890	Gravity; rock and gravel dam with 0.4 mile of earth ditch.	Former owner: Nelson Chisholm. Amount diverted irrigated an additional 143 acres jointly with 42N/6W-19A1 (Willow Creek Subunit).
42N/6W-9R1 (Sheet 11)	Dan Shelley	Willow Creek	Irrig.	46 acres by flooding	40	Riparian	--	--	1860	Gravity; rock and gravel dam with 0.2 mile of earth ditch.	Former owner: Mary Finnerty.
42N/6W-10L1 (Sheet 11)	Glen G. Maxwell	Willow Creek	Irrig.	8 acres by flooding	80	Riparian	--	--	Prior 1958	Gravity; 0.1 mile of earth ditch.	
42N/6W-16C1 (Sheet 11)	Dan Shelley	Willow Creek	Irrig.	29 acres by flooding*	120*	Riparian	--	--	1875	Gravity; 0.3 mile of earth ditch.	Former owner: Nelson Chisholm. Amount diverted irrigated an additional 98 acres jointly with 42N/6W-19A1 (Willow Creek Subunit).
42N/6W-16E1 (Sheet 11)	Howard Dameron	Willow Creek	Irrig.*	(*)	None	Adjud.	2.40 cfs ^h	Par. 158 ^g	Prior 1880	Gravity; rock dam 3 feet high, 15 feet long with 0.2 mile of earth ditch.	Former owners: M. E. Harris, Van Horn, Chamberlain, Johnson, Richardson. Previously irrigated 62 acres.

<u>M D B & M</u>											
43N/5W-6D1 (Sheet 9)	Grenada Irrigation District	Shasta River	Irrig.	1,541 acres by flooding	6,268	Approp.	40 cfs	Appl. 448 ^c	1898	**	**
43N/5W-6D2 (Sheet 9)	Huesman Ditch Frank Brahs Tom De Sozo Jerald Jenkins H. J. Peters Mrs. Roof	Shasta River	Irrig.	1,176 acres by flooding	9,077 ^a	Adjud.	11.90 cfs ^a 5.00 cfs ^a	Par. 124 ^g	1862	Gravity; wood gate 5 feet high, 5 feet long with 12 miles of earth ditch and 3 storage reservoirs.	**Former owners: Edison and Foulke Company, Manuel De Sozo. Portion of amount diverted irrigated an additional 202 acres jointly with 44N/6W-25F1, 11.90 cfs April 1 to October 1, 5.00 cfs October 1 to April 1.
43N/6W-2F1 (Sheet 8)	Samuel Bruinsma	Willow Creek	Irrig.*	(*)	None	Riparian	—	—	Prior 1958	Gravity; concrete headgate 2 feet high, 4 feet long with 0.4 mile of earth ditch.	Former owners: Orr Brothers, Orr Estate, D. H. McGargar. Previously supplemented 43N/6W-2L1.
43N/6W-2L1 (Sheet 8)	Samuel Bruinsma	Willow Creek	Irrig.	179 acres by flooding ^a	338	Riparian	—	—	Prior 1958	Gravity; wood headgate with 0.4 mile of earth ditch.	Former owners: Orr Brothers, Orr Estate, D. H. McGargar. Area irrigated previously received supplemental supply from 43N/6W-2F1.
43N/6W-11B1 (Sheet 8)	Samuel Bruinsma	Willow Creek	Irrig.	12 acres by flooding	244	Riparian	—	—	Prior 1958	Gravity; concrete headgate 2 feet high, 4 feet long with 0.3 mile of earth ditch.	Former owners: Orr Brothers, Orr Estate, D. H. McGargar.
43N/6W-11G1 (Sheet 8)	Samuel Bruinsma	Willow Creek	(*)	(*)	434	Adjud.	0.10 cfs ^b	Par. 112 ^g	Prior 1958	Gravity; earth dam 2 feet high, 50 feet long with 2.2 miles of earth ditch.	Former owner: W. D. Duke. Purpose of diversion in year of survey was leaching an alkali field.
43N/6W-14N1 (Sheet 8)	J. L. Price	Tributary to Willow Creek	Irrig.	(*)	20 ^a	(b)	—	—	1946	Pump; 10 hp motor with a short pipeline.	Amount diverted supplemented 43N/6W-23N1.
43N/6W-22R1 (Sheet 8)	J. L. Price	Springs tributary to Willow Creek	Irrig.	(*)	40 ^a	(b)	—	—	About 1850	Pump; 20 hp motor with a short pipeline.	Amount diverted supplemented 43N/6W-23N1.
43N/6W-23N1 (Sheet 8)	J. L. Price	Orr Slough	Irrig.	(*)	544 ^a	Riparian	—	—	1944	Gravity; earth dam 7 feet high, 150 feet long with 0.8 mile of earth ditch. A sump at base of dam 200 feet long, 40 feet wide, 20 feet deep has a short earth ditch to connection with 43N/6W-26C1 and a 10 hp pump with 50 feet of 6-inch pipe to 1.6 miles of earth ditch from dam.	Former owner: Richard Richman. Previously irrigated an additional 18 acres. Amount diverted combined with the water supply from 43N/6W-14N1 and 43N/6W-22R1, and irrigated 621 acres jointly with 43N/6W-26C1.
43N/6W-25D1 (Sheet 8)	Edson L. Foulke	McCloud Slough	Irrig.	114 acres by flooding	Not meas.	Adjud.	2.00 cfs ^b 1.00 cfs ^b	Par. 122 ^g	About 1856	Gravity; timber dam 20 feet long, 4 feet high with 0.5 mile of earth ditch.	Former owner: Edison and Foulke Company. Reported water right amounts may be diverted all or in part by this diversion, 43N/6W-26B1, or 43N/6W-26H2.

- h. Reported amount to be diverted between March 1 and November 1.
- j. Reported amount to be diverted between November 1 and March 1.
- k. Partial record during 1958.

measure the flows. Results of these measurements are reported in Table 6 and are summarized below. Substantially, all diversion measurements were started by April 1958, prior to the commencement of intensive irrigation, and continued to obtain a complete season's record. The measurements were classed as estimates when data were incomplete or uncertain. If diversions were located late in the survey so that measurements could not be made during part of the season, this is also indicated in the table. Diversions for which no measurement or estimate was possible were omitted from the table. When feasible, measurements of each diversion were made at a location above the area of first use and as close to the diversion intake as possible, but below any regulatory spill. Exceptions are noted in the table.

The total measured amount of water diverted was about 282,200 acre-feet, of which 276,800 acre-feet were for irrigation, 1,000 acre-feet for power production, 100 acre-feet for recreation, 1,400 acre-feet for municipal purposes, and 2,900 acre-feet for industrial uses.

Diverted quantities were determined primarily by measurement of open channel flow and testing of pumps. Periodic current meter measurements of open channel flow were made during the diversion season to obtain channel ratings. The water stage was recorded either by weekly observations of a staff gage or with a continuous recorder, from which quantities of flow were calculated. Existing Parshall flumes or weirs were used whenever available. Pumps were similarly rated and quantities of flow calculated from operation or power records.

In Table 6 the superscript "e" indicates that at least 10 days' record within the month was estimated. If insufficient data were available to report monthly values, but an estimate was made for the total period, this is indicated as "-----**-----." If no record was available on which to make an estimate, this is indicated as "-----NR-----." When the diversion for a given period is known to have been zero, it is so indicated. Notations regarding extent of irrigation period indicate the overall period of irrigation, but not necessarily that daily or continuous irrigation was practiced throughout the period. Notations that a stream source was "dry" at a certain time indicate that the source was essentially dry, and that streamflow was so low as to make diversion infeasible.

The total amount of water measured during 1958 was 282,200 acre-feet, diverted for all purposes, as shown in Table 6. To obtain a representative estimate of the overall rate of water use per acre, 22,300 acres were selected that were irrigated by surface water only. Approximately 141,300 acre-feet of water were diverted for the irrigation of these 22,300 acres during the irrigation season, April through September, at an overall rate of 6.3 acre-feet per acre. This does not include estimated diversion totals for which monthly values are unknown. However, minor domestic and stockwatering uses in conjunction with irrigation were included. The seasonal diversion rates of individual diversion systems varied from less than 1 to over 50 acre-feet per acre.

Index to Surface Water Diversions

For convenience of the reader, an alphabetical index of diversion owners and diversion names, along with the subunit

location of each diversion and references to map and page numbers on which data concerning each appear, is shown in Table 7.

Imports and Exports

Surface water was imported to the Shasta-Scott Valleys Hydrographic Unit through the Hammond North Fork Ditch (40N/5W-21C1) from the Shasta Lake Hydrographic Unit. A total of 1,558 acre-feet was imported during 1958. No surface water was exported from the unit.

Consumptive Use

In the Shasta-Scott Valleys Hydrographic Unit, the largest consumptive use of applied water is for irrigated agriculture. Consumptive use of water is defined as water consumed by vegetative growth in transpiration and building of plant tissue, and by water evaporated from adjacent soil, from water surface, and from foliage. It also includes water similarly consumed and evaporated by urban and nonvegetative types of land use.

Based on the land use surveys presented in this bulletin, and on the unit consumptive use values given in Department of Water Resources Bulletin No. 83, "Klamath River Basin Investigation," which are tabulated below, the total consumptive use of applied water during 1958 is estimated to have been 42,820 acre-feet, of which 39,430 acre-feet were used for irrigated agriculture, 1,760 acre-feet for domestic and municipal purposes, and 1,630 acre-feet for industrial purposes in the production of lumber, plywood, and other wood products. The consumptive use of water

CHAPTER III. LAND USE

A thorough understanding of historic and present land and water uses in Shasta-Scott Valleys Hydrographic Unit is essential to the determination of future water requirements in the area. The results of a survey of surface water facilities were presented in Chapter II. The results of a 1958 survey of present land uses are presented in this chapter.

Historical Land Use

The Shasta-Scott Valleys Hydrographic Unit, located in Siskiyou County, has followed a development pattern closely related to that of the county. Siskiyou County was formed by the State Legislature in 1852 from parts of Shasta County and the since-dissolved Klamath County. The California-Oregon Trail, a pack trail for gold miners in the early 1850's and a state route in the later 1850's, brought many pioneers and adventurers into and through the county's valleys and mountains.

Gold mining activities resulted in a rapid increase in population during the 1850's. However, as was the case in other gold mining areas of the State, a decline in population followed the depletion of the more readily accessible ore deposits.

During its early development period, agricultural production in Siskiyou County was characterized as self-sufficient and, because production was used largely for local consumption, it was relatively diversified. Aided by the presence of plentiful, cheap, and fertile land, agriculture was sufficiently developed by 1869 to support agricultural fairs in the county,

wherein field crops, orchards, dairies, and livestock were represented. The local demand for agricultural products created by the miners in the area then began to subside, and by 1877 the reduction in gold production had so seriously affected the local market for agricultural output that wool, butter, and flour were being shipped to the Sacramento Valley. Between 1869 and 1877, butter and cheese production declined, while hay and fruit production increased. During this time, the principal products were small grains, corn, beans, peas, potatoes, and other vegetables.

After 1900 the shift to beef cattle production in Siskiyou County was accelerated, and farm holdings became larger and less numerous. Total acreage in farm holdings increased from 455,900 acres in 1900 to 537,400 acres in 1920, while improved acreage declined from 186,100 to 166,600. Value of livestock on farms increased from \$1,280,000 in 1900 to \$2,085,000 in 1910, and to \$3,788,000 in 1920. Principal crops in the county in 1920, in order of value, were hay and forage, cereals, vegetables, fruits, and nuts. Between 1910 and 1920, the land area under irrigation increased from 60,300 to 65,600 acres, and the number of irrigation systems increased from 455 to 572.

The lumber industry in Siskiyou County has existed since shortly after the county was formed, with Weed being the center of lumbering activity since about 1900. Lumber production has tended to follow the cycles of general business activity, and was relatively active in the 1920's, relatively inactive in the 1930's, and very active since 1945. Production since 1945 has increased from an annual output of 172 million board feet in that year, to an estimated 558 million board feet in 1958.

Present Land Use

A detailed land use survey was conducted in the Shasta-Scott Valleys Hydrographic Unit during the spring of 1958, in which the area was mapped according to the uses of the land, such as irrigated agriculture, dry-farmed agriculture, urban development, or recreational development. The results of this survey are presented on Sheets 1 through 18 of Plate 2, "Land and Water Use, Shasta-Scott Valleys Hydrographic Unit." The areas of land use within each subunit are listed in Table 8.

Methods and Procedures

The survey was accomplished by plotting field observations on aerial photographs having a scale of approximately 1 to 20,000. As the present use of each parcel of land was determined, it was delineated on the aerial photographs. The area was traversed by automobile as completely as roads and trails permitted. This coverage was supplemented by inspection on foot and stereoscopic studies of the photographs in areas not easily accessible. An example of an aerial photograph with delineated land use data is shown on page 134.

After completion of field mapping on these photographs, the delineations were transferred to U. S. Geological Survey quadrangle sheets at a scale of 1 to 24,000, in order to bring the various delineated areas to a common scale. The scale of aerial photographs is not uniform and changes rapidly in mountainous areas where there is considerable variation in elevation. After projection onto the quadrangle maps, the area of each

parcel of land was determined. These are gross areas without reduction for roads, farmsteads, canals, and other rights-of-way which occur within the mapped areas.

Irrigated Lands

Irrigated lands, as presented in this report, include all agricultural lands which receive applied water. The area irrigated within each subunit is reported in Table 9 by diversion and by crop. Although the irrigated lands are tabulated under the name of the subunit within which the lands are located, it should be noted that the diversion serving the lands may originate in another subunit.

In Table 9, irrigated lands are segregated into pasture, alfalfa hay and pasture, grain, hay, truck and field crops, orchard, and into those lands which are normally irrigated but which were idle or fallow during the year of survey. Pasture lands are subdivided into mixed, native, and meadow pasture, the latter comprising native pasture lands having a high water table induced by application of irrigation water. Grain is subdivided into barley, wheat, and oats. Hay is subdivided into alfalfa hay, and miscellaneous and mixed hay and grain. Truck crops are subdivided into potatoes and miscellaneous truck. Field crops are subdivided into sugar beets and corn. Orchard is subdivided into apples and miscellaneous deciduous.

On the land and water use maps, Plate 2, lands irrigated by surface water are shown in three categories: (1) those which received a full irrigation in 1958, (2) those which received

a - Received partial irrigation.

only a partial irrigation because of insufficient water supply, and (3) those lands usually irrigated but which were idle or fallow in 1958. Lands irrigated by ground water are separately delineated.

Naturally High Water Table Lands

In addition to the lands which receive applied water as described above, there are lands supporting vegetation utilizing water from a naturally high water table, such as mountain meadows or lands adjacent to lakes and streams. These are shown in Table 8 as "Meadowlands," and on Plate 2 as "naturally irrigated meadowlands." If standing water is observable in an area on which tules, cattails, bullrushes, and similar vegetation is growing, the area is shown in Table 8 and on Plate 2 as "Marshlands."

Dry-Farmed Lands

Dry-farmed lands are those cropped areas which do not receive water in excess of natural precipitation, and lands that are normally planted to dry-farmed crops but which at the time of the survey were tilled but not planted, i.e., fallow lands. Also included in this category are lands formerly dry-farmed, but which were lying idle at the time of the survey. If a field had been idle long enough to revert to its native condition, it was mapped as native vegetation. Dry cattle rangelands which are indistinguishable from lands with native cover, not used for grazing purposes, are similarly mapped as native vegetation. Water used in both cases is identical and is dependent upon precipitation.

Irrigating Alfalfa, Scott Valley

Department of Water Resources Gaging Station, "Little Shasta River Near Montague"

Urban Lands

Urban lands include the total areas of cities and towns, small communities, and industrial areas of approximately 3 acres or more. These are gross delineations, including streets and vacant lots. The lower density limit used to identify urban lands in this survey was one residence per 2 acres.

Recreational Lands

Recreational lands include camp and trailer sites, resorts, and permanent and summer homes in predominantly recreational areas, as well as motels and other commercial establishments which provide services to such areas. This category also includes parks located outside delineated urban areas. As in the case of urban lands, these delineated areas are not necessarily fully developed.

Native Vegetation

Lands which are essentially in a native state, and not included in any of the above categories, as well as scattered residences and other isolated uses too small to be delineated, were mapped as "native vegetation." However, in addition to the lands so mapped, the total acreage reported in this native vegetation category includes lands which were mapped as water surface and farm building areas, including dairies, feed lots, etc. The total of all these lands was some 800,000 acres, or about 86 percent of the Shasta-Scott Valleys Hydrographic Unit, in 1958. Most of these lands, even in their native state, are used for commercial timber production, livestock range, and recreational activities such as fishing, hunting, hiking, and picnicking.

CHAPTER IV. LAND CLASSIFICATION

Calculations of future water requirements will be based in part on a classification of lands with regard to their potential for irrigated agricultural and recreational development. The results of such a land classification survey in the Shasta-Scott Valleys Hydrographic Unit are presented in this chapter.

The former Division of Water Resources made a reconnaissance classification of lands of the State which was reported in State Water Resources Board Bulletin No. 2. A more detailed land classification survey was performed by the department and reported in Department of Water Resources Bulletin No. 83, "Klamath River Basin Investigation," dated May 1960, and Bulletin No. 58, "Northeastern Counties Investigation," dated June 1960. The area of the Shasta-Scott Valleys Hydrographic Unit was included in each of these bulletins. The present investigation uses the same basic land classification survey which was used in Bulletins Nos. 83 and 58, but additional data on classification of recreational lands have been included, along with some minor modifications to the irrigable agricultural lands, and a remapping of the present urban lands.

Lands were not classified in this survey with respect to their potential for urban development. The use of lands for urban purposes is closely related to population at any given time, and it is planned to defer designation of these lands until estimates of population and related economic studies are made in connection with determinations of future water requirements.

Methods and Procedures

Lands were classified by field inspection. The areas were mapped on aerial photographs in the field, and the total area of each parcel of land was determined by methods similar to those described for the survey of present land use.

The standards used in the classification of lands are given in detail in Table 10.

Results of the land classification survey are delineated on Plate 3, "Classification of Lands, Shasta-Scott Valleys Hydrographic Unit," sheets 1 through 18. The areas of land classification within each subunit are shown in Table 11.

TABLE 10
LAND CLASSIFICATION STANDARDS

Land : class : symbol:	Characteristics
------------------------------	-----------------

Irrigable Lands

- V - These lands are level or slightly sloping, and vary from smooth to hummocky or gently undulating relief. The maximum allowable slope is six percent for smooth, reasonably large-sized bodies lying in the same plane. As the relief increases and becomes more complex, lesser slopes are limiting. The soils have medium to deep effective root zones, are permeable throughout, and are free of salinity, alkalinity, rock, or other conditions limiting crop adaptability of the land. These lands are suitable for all climatically adapted crops.
- H - These are lands with greater slope and/or relief than those of the V class. They vary from smooth to moderately rolling or undulating relief. The maximum allowable slope is 20 percent for smooth, reasonably large-sized bodies lying in the same plane. As the relief increases and becomes more complex, lesser slopes are limiting. The soils are permeable, with medium to deep effective root zones, and are suitable for the production of all climatically adapted crops. The only limitation is that imposed by topographic conditions.

Example of Land Classification Delineated on Aerial Photograph
(See page 176 for symbol explanation)

TABLE 10 (continued)

LAND CLASSIFICATION STANDARDS

Land : class : symbol:	Characteristics
M -	These are lands with greater slope and/or relief than those of the H class. They vary from smooth to steeply rolling or undulating relief. The maximum allowable slope is 30 percent for smooth, reasonably large-sized bodies lying in the same plane. As the relief increases and becomes more complex, lesser slopes are limiting. The soils are permeable, with medium to deep effective root zones, and are suitable for the production of all climatically adapted crops. The only limitation is that imposed by topographic conditions.
Any variation from the foregoing, as defined, is indicated by use of one or more of the following symbols:	
w -	Indicates the presence of a high water table, which in effect limits the present crop adaptability of these lands to pasture crops. Drainage and a change in irrigation practice would be required to affect the crop adaptability.
s -	Indicates the presence of an excess of soluble salts or exchangeable sodium in slight amounts, which limits the present adaptability of these lands to crops tolerant to such conditions. The presence of salts within the soil generally indicates poor drainage and a medium-to-high water table. Reclamation of these lands will involve drainage and the application of small amounts of amendments, and some additional water over and above crop requirements, in order to leach out the harmful salts.
ss -	Indicates the presence of an excess of soluble salts or exchangeable sodium in sufficient quantity to require the application of moderate amounts of amendments and some additional water over and above crop requirements, in order to effect reclamation.
h -	Indicates very heavy textures, which make these lands best suited for production of shallow-rooted crops.
l -	Indicates fairly coarse textures and low moisture-holding capacities, which, in general, make these lands unsuited for the production of shallow-rooted crops because of the frequency of irrigations required to supply the water needs of such crops.
p, -	Indicates shallow depth of the effective root zone, which limits use of these lands to shallow-rooted crops.

TABLE 10 (continued)
LAND CLASSIFICATION STANDARDS

Land :	
class :	Characteristics
symbol:	

- r - Indicates the presence of rock on the surface or within the plow zone in sufficient quantity to prevent use of the land for cultivated crops.

Urban Lands

- UD - The total area of cities, towns, and small communities presently used for residential, commercial, recreational, and industrial purposes.

Recreational Lands

- RR - Existing and potential permanent and summer home tracts within a primarily recreational area. The estimated number of houses, under conditions of full development, is indicated by a number in the symbol, i.e., RR-3 is suitable for three houses per acre.
- RC - Existing and potential commercial areas which occur within a primarily recreational area and which include motels, resorts, hotels, stores, etc.
- RT - Existing and potential camp and trailer sites within a primarily recreational area.
- P - Existing and potential county, state, federal, and private parks, racetracks, and fairgrounds.

Miscellaneous Lands

- F - Presently forested lands, or lands subject to forest management, which meet the requirements for irrigable land but which, because of climatic conditions and physiographic position, are better suited for timber production or some type of forest management program, rather than for irrigated agriculture.
- Vm - Swamp and marshlands which usually support a heavy growth of phreatophytes, and are covered by water most of the time.
- N - Includes all lands which fail to meet the requirements of the above irrigable, urban, and recreational and miscellaneous classes.
-

Major Categories of Land Classes

The lands mapped can be grouped into four major categories: (1) irrigable lands, (2) urban lands, (3) recreational lands, and (4) miscellaneous lands: irrigable lands deemed best suited to remain under forest or range management, marshlands, and all those lands which fail to meet the requirements of the first three land class categories.

Irrigable Lands

Irrigable lands are classified according to their suitability for development under irrigated agriculture, and to their crop adaptability. Presently irrigated lands are included, but urban lands and recreational lands are not classed as to irrigability. In this survey, only physical characteristics of the land were considered. The time element with respect to when the lands might be developed did not enter the determination, except that suitability for irrigated agriculture was necessarily considered in light of present agricultural technology.

There are many factors which influence the suitability of land for irrigation development. Soil characteristics and physiography are the most stable aspects of the land, and were therefore considered in classifying lands as to irrigability. Other factors, such as the production and marketing of crops, the location of lands with respect to a water supply, and climatic conditions, were not considered in the basic classification. These latter factors are very important in estimating the nature of future cropping patterns and practices, and will be given due consideration when estimates are made of future water requirements.

Feed Mill, Montague

Stacking Lumber for Air Drying, Yreka

Urban Lands

As previously stated, the lands of Shasta-Scott Valleys Hydrographic Unit were not classified with respect to their potential urban use. Only those lands devoted to urban uses in 1958 are designated herein as "urban" lands.

Recreational Lands

Present trends indicate an expanding rate of use and demand for recreational facilities throughout the State. In view of these trends and the ever-increasing population, it is recognized that there will be a demand for substantial land areas for recreational purposes. This is particularly true of the mountainous regions, where this type of development is expanding rather rapidly at the present time.

Generally speaking, all mountainous lands are suitable for some recreational use such as hunting, fishing, and similar outdoor activities. However, for purposes of this investigation, only those lands which are now, or in the future may be, used intensively for permanent and summer home tracts, commercial areas, camp and trailer sites, and parks outside of urban areas, were classified for recreational use.

Lands suitable for potential recreational areas were classified by field observation. Primary considerations were such physical factors as soil depth, slope, and rockiness; such aesthetic values as view, nearness to lakes or streams, or density and type of forest canopy suitable for the respective uses; and the plans of federal and state forest officials. The availability of an existing water supply was an important factor in classification

of camp and trailer sites, but isolation from existing roads did not influence such classification.

Miscellaneous Lands

Presently forested lands or lands best suited for forest management which are otherwise irrigable are classed as "F" lands. Lands which were designated in the land use survey as "marshlands" are classified as "Vm" lands.

Lands which failed to meet the requirements previously described in this chapter are herein called "miscellaneous," and amounted to approximately 708,000 acres, or 76 percent of the unit. These "other lands" are not shown in Table 11.

CHAPTER V. SUMMARY

The Shasta-Scott Valleys Hydrographic Unit, which contains 1,456 square miles of central Siskiyou County, lies within the Klamath River Basin of the North Coastal area. It includes the entire watershed of the Shasta River and that portion of the Scott River watershed which is above the gaging station "Scott River near Fort Jones," some 20 miles above the confluence of the Scott and Klamath Rivers. Shasta Valley, with a north-south length of about 30 miles, and a maximum width of about 15 miles, has an area of about 220 square miles, and varies in elevation from 2,500 feet near Montague to 3,000 feet near Edgewood.

Scott Valley, which has a north-south length of about 20 miles, is narrow at its southerly upstream section near Callahan, and has a maximum width of 7 miles near Greenview. Its area is about 100 square miles and, like Shasta Valley, varies in elevation from 2,500 feet to 3,000 feet above sea level. The rugged mountains surrounding the two valleys comprise the remaining 1,136 square miles of the hydrographic unit.

Valley and foothill lands constitute about 24 percent of the total area. Agriculture is the largest single commercial enterprise in the unit. Approximately one-third of the presently cultivated lands are dry-farmed, and two-thirds are irrigated. The major irrigated crops are pasture and grain. Lumbering and associated wood products manufacturing are additional important local activities. The largest town in the unit is Yreka, with a 1960 population of about 5,000.

Water Use

Most of the water rights in Shasta Valley and some of the water rights in Scott Valley have been adjudicated by legal action, and others have been defined by private agreements. The remaining use is based primarily on riparian rights, or on appropriative rights established prior to 1914, by merely diverting and using the water.

As of June 28, 1960, a total of 68 active applications to appropriate water in the unit were on file with the State Water Rights Board. Permits or licenses were granted for 66 of these applications, and 2 were incomplete.

Approximately 73 percent of the 541 surface water diversions located were measured during 1958. The primary uses and amounts diverted are summarized below:

<u>Primary use</u>	<u>Diversions located</u>	<u>Diversions measured</u>	<u>Amount measured (acre-feet)</u>
Irrigation	524	387	276,800
Municipal	11	4	1,400
Industrial (lumber mills)	3	2	2,900
Power	2	1	1,000
Recreation (golf course)	<u>1</u>	<u>1</u>	<u>100</u>
TOTALS	541	395	282,200

The total consumptive use of applied water during 1958 is estimated to have been 42,820 acre-feet, of which 39,430 acre-feet were used for irrigated agriculture, 1,760 acre-feet for domestic and municipal purposes, and 1,630 acre-feet for industrial purposes in the production of wood products.

Land Use

The areas of present land uses within the Shasta-Scott Valleys Hydrographic Unit are summarized below. They are shown on Plate 2 and illustrated graphically by the pie-chart in Figure 1.

<u>Use</u>	<u>Area, in acres</u>
Agricultural lands	
Lands irrigated in 1958	79,200
Lands normally irrigated but idle or fallow in 1958	3,140
Meadowlands	3,920
Marshlands	1,480
Dry-farmed lands	<u>40,590</u>
TOTAL	128,330
Recreational lands	70
Urban lands	3,280
Native vegetation	<u>800,220</u>
TOTAL AREA OF UNIT	931,900

Land Classification

The land classification survey reported in Department of Water Resources Bulletins Nos. 58 and 83 was used in this investigation, with additional data on classification of recreational lands, some minor modifications to the irrigable agricultural lands, and a resurvey of present urban lands. The results of these surveys are summarized below. They are shown on Plate 3, and are illustrated graphically by the pie-chart in Figure 2.

<u>Classification</u>	<u>Area, in acres</u>
Irrigable agricultural lands	219,050
Recreational lands	1,910
Present urban lands	3,280
Miscellaneous lands	
Irrigable forest management lands	33,060
Other lands (including "Vm" lands)	<u>674,600</u>
TOTAL AREA OF UNIT	931,900

APPENDIX A

STATEWIDE WATER RESOURCES AND WATER
REQUIREMENTS PROGRAM

APPENDIX A

STATEWIDE WATER RESOURCES AND WATER REQUIREMENTS PROGRAM

California's major water problem today is that of development and delivery of supplemental water supplies to meet increasing water requirements throughout the State. The problem involves (1) the regulation of seasonal and cyclic fluctuation of streamflow to meet demand schedules in the areas of origin, and (2) the transmission of regulated surplus flows over long distances to areas of deficiency. The development and long distance transfer of water is currently accomplished by such major facilities as the federal Central Valley Project and the Colorado River Aqueduct of The Metropolitan Water District of Southern California. However, such development and transfer will be considerably broadened in scope by the State Water Facilities.

Consumptive water requirements of the State on a basin-wide basis were estimated in State Water Resources Board Bulletin No. 2, "Water Utilization and Requirements of California," June 1955. However, to provide for local water needs while considering specific export projects, more detailed information must be made available on present and projected future water requirements of the areas in which the projects are to be built. This will necessitate considerably more detailed collection and analysis of data on the hydrology, land use, land capability, and economics.

APPENDIX A

STATEWIDE WATER RESOURCES AND WATER REQUIREMENTS PROGRAM

California's major water problem today is that of development and delivery of supplemental water supplies to meet increasing water requirements throughout the State. The problem involves (1) the regulation of seasonal and cyclic fluctuation of streamflow to meet demand schedules in the areas of origin, and (2) the transmission of regulated surplus flows over long distances to areas of deficiency. The development and long distance transfer of water is currently accomplished by such major facilities as the federal Central Valley Project and the Colorado River Aqueduct of The Metropolitan Water District of Southern California. However, such development and transfer will be considerably broadened in scope by the State Water Facilities.

Consumptive water requirements of the State on a basin-wide basis were estimated in State Water Resources Board Bulletin No. 2, "Water Utilization and Requirements of California," June 1955. However, to provide for local water needs while considering specific export projects, more detailed information must be made available on present and projected future water requirements of the areas in which the projects are to be built. This will necessitate considerably more detailed collection and analysis of data on the hydrology, land use, land capability, and economics.

Recognizing that additional information is needed if the water needs of areas of origin are to be adequately protected in large-scale water development projects, the 1956 Legislature authorized an investigation to determine the water resources and water requirements of the respective watersheds in the State. The authorization is contained in Chapter 61, Statutes of 1956, as amended by Chapter 2025, Statutes of 1959. This legislation is codified in Section 232 of the Water Code as follows:

"232. The Legislature finds and declares that in providing for the full development and utilization of the water resources of this State it is necessary to obtain for consideration by the Legislature and the people, information as to the water which can be made available for exportation from the watersheds in which it originates without depriving those watersheds of water necessary for beneficial uses therein. To this end, the department is authorized and directed to conduct investigations and hearings and to prepare findings therefrom and to report thereon to the Legislature at the earliest possible date with respect to the following matters:

- (a) The boundaries of the respective watersheds of the State and the quantities of water originating therein;
- (b) The quantities of water reasonably required for ultimate beneficial use in the respective watersheds;
- (c) The quantities of water, if any, available for export from the respective watersheds;
- (d) The areas which can be served by the water available for export from each watershed; and
- (e) The present use of water within each watershed together with the apparent claim of water right attaching thereto, excluding individual uses of water involving diversions of small quantities which, in the judgment of the Director of Water Resources, are insufficient in the aggregate to materially affect the quantitative determinations included in the report.

"Before adopting any findings which are reported to the Legislature, the department shall hold public hearings after reasonable notice, at which all interested persons may be heard."

For purposes of this inventory, the State has been divided into major hydrographic areas. These areas, in turn, have been subdivided into hydrographic units generally comprising watersheds of individual rivers. Basic data on present water uses, together with the apparent claim of water right attached thereto, present land uses, history of land and water uses, and the classification of lands will be presented separately for each hydrographic unit in this series of reports on land and water use. Bulletin No. 94-5, "Land and Water Use in Shasta-Scott Valleys Hydrographic Unit," is the fifth of a series reporting the results of these surveys.

At a future date, estimates, based largely on the land and water use surveys, will be made of quantities of water reasonably required for future beneficial use in each watershed. The quantity of water potentially available for export from each watershed will be determined after allowances are made for the satisfaction of the local requirements and prior rights to divert water to other areas. For those watersheds in which no exportable water is available, the water supply deficiency will be determined. These estimates will be published as they become available, in such form as to make possible a county-by-county determination.

Calculations of future water requirements will be based on predicted future land uses derived from land classification surveys, economic studies, population forecasts, industrial

and agricultural development, and recreational needs. Agricultural water requirements will be based on unit water use by the various predicted crop types; urban and recreational requirements on per capita water use values; fish and wildlife requirements on the amount of streamflow needed, or the water demands for wildlife; and industrial water requirements on measured water deliveries to various types and sizes of industries now existing. In forecasting future industrial development, water quality problems will be given full consideration.

Water resources will be determined from records of all stream gaging stations, including new stations which were established for this and other investigations of the department. The new stations were generally constructed on streams which originate in the smaller watersheds, for which runoff data are necessary, but for which no data have been available.

-----	---	------

APPENDIX C

LEGAL CONSIDERATIONS

There are set forth in the following paragraphs brief general statements with respect to the California law of water rights, to supplement, and to provide a background for information on water rights contained in Chapter II. Also included is a tabulation of currently valid applications to appropriate water within Shasta-Scott Valleys Hydrographic Unit filed with the State Water Rights Board.

California Water Rights

All rights to water in California are usufructuary. They consist only in right to the beneficial use of the water. Water itself is subject to ownership only when it has been taken into actual possession. However, the owner of an usufructuary right is entitled to have the water in the surface stream flow to the point of his diversion, or to his riparian lands, without the unlawful interference by upstream diverters who have rights which are inferior to his.

Riparian and appropriative rights to surface water are recognized in California. Riparian rights are paramount until lost or impaired by grant, condemnation, or prescription. Correlative rights to ground water, also recognized in California, are analogous to the riparian rights to surface waters.

All water rights, both surface and underground, are subject to the doctrine of reasonable use, expressed in Section 3 of Article 14 of the State Constitution. This doctrine limits

the rights to the quantity of water reasonably required for beneficial use, and prohibits waste, unreasonable use, or unreasonable methods of use or diversion.

Riparian Rights

Riparian rights are part and parcel of riparian lands, i.e., lands contiguous to a natural watercourse within a watershed. They extend only to the smallest tract, so situated, held within the continuous chain of ownership. Each riparian right is correlative with each and every other such right within the watershed. In the event of insufficient water for all, the available supply must be prorated, except that an upper riparian owner may take the whole supply if necessary for domestic use. Riparian rights extend to future reasonable requirements for beneficial use upon riparian lands.

Riparian rights do not authorize use of water on non-riparian lands, nor do they permit the seasonal storage of water. They are not created by use nor are they lost by nonuse. They do not prevent temporary appropriation by others of water not presently needed on riparian lands. The rights may be severed or lost, in the whole or in part, by grant or condemnation, and they cannot thereafter be restored. A parcel of land loses its riparian right when separated from contact with a stream by conveyance, unless the right is specifically reserved by the grantor. Riparian rights cannot be transferred for use upon another parcel of land. A riparian right may also be lost by prescription.

Riparian rights are superior to appropriative rights, except in the case of rights founded upon appropriations of water upon vacant public lands initiated before valid steps were taken to remove the riparian lands from the domain of the United States, regardless of whether the appropriative diversions and/or the lands they serve are upstream or downstream from the riparian lands.

Appropriative Rights

The miners of the early gold seeking period established the doctrine of appropriative water rights in California. The oldest of the procedures to perfect an appropriative right required simply that a diversion be made and the water be put to beneficial use. The date of the right began with its beneficial use.

The first provision for recordation as a step in perfecting an appropriative water right was contained in the Civil Code enacted in 1872, Section 1415. The procedure under this section was the posting of a notice of intention at or near the place of proposed diversion, describing the source of the water, the location of the proposed diversion, the amount to be diverted, the use to be made, and the place of use. This notice was to be signed, witnessed, and a copy filed with the recorder in the county in which the proposed diversion was located. The appropriative right thus initiated became perfected when the water was put to beneficial use, but the right related back to the time the notice was posted. While the 1872 Civil Code procedure was the first to

require recordation, it was not an exclusive procedure, in that an appropriative right could be perfected to the extent of beneficial use simply by diverting the water and making beneficial use of it.

The Water Commission Act, on the other hand, established an exclusive procedure for the appropriation of water. This enactment requires that a permit be obtained from the State of California before water can be appropriated. The procedure, as formerly contained in the Water Commission Act, and as subsequently amended, is now codified in Water Code Sections 1200-1801. It requires that an application to appropriate water first be submitted to the State Water Rights Board. When the project has been completed, an inspection of it is made, and a license is issued, to the extent of beneficial use, provided the terms and conditions of the permit have been fulfilled.

Once an appropriative water right has been initiated, it must be diligently prosecuted to completion, in order to maintain its date of priority. While water may not be appropriated for a distant future use, a reasonable amount of time is allowed to put the full amount of water to use within the original intent of the application to appropriate water.

A right to appropriate water is lost by abandonment or continuous nonuse. In the case of an appropriation initiated prior to 1914, the period of continuous nonuse generally is five years, while in the case of an appropriation initiated under the Water Commission Act or the Water Code, the period of continuous nonuse is generally only three years. Domestic use of water is the highest use, and irrigation next highest use of water, as provided in the Water Code.

Applications to appropriate water within the Shasta-Scott Valleys Hydrographic Unit, filed with the State Water Rights Board, and active on June 28, 1960, are summarized in Table C-1, page C-13. Diversion identification numbers, explained in Chapter II, are shown, corresponding to the appropriate application where a significant diversion was made under the application.

Correlative Rights to Ground Water

The permit and license procedure established by the Water Commission Act applies only to streams and other bodies of surface water and to subterranean streams flowing through known and definite channels. Percolating ground water is therefore excluded, and rights to its use are governed by judicial decisions rather than by statute. Ground waters are presumed to be percolating in the absence of evidence to the contrary.

The owner of land overlying a ground water basin or stratum has, like the riparian owner, a paramount right to the reasonable beneficial use of the natural supply upon his overlying land, which right he holds in common with all other landowners similarly situated. Only surplus water in excess of reasonable requirements for beneficial use upon overlying lands is subject to appropriation for beneficial use upon other lands. Prescriptive rights to ground water may be acquired under the same circumstances as prescriptive rights to water of surface streams.

Where ground water and surface water are interconnected, one acting as a tributary to the other, both are treated as part of a common supply, and users of water from either source are

entitled to protection from substantial injury as a result of use by others of water from the other source. Thus, an owner of land riparian to a stream may have his right to the use of water protected against impairment by an appropriator of percolating ground water tributary to the stream and required for the maintenance and support of its flow. Likewise, where water from a stream percolates to a ground water basin or stratum, the owner of land overlying such ground water may be protected from an appropriation of water of the stream, if such use causes a substantial impairment of the ground water supply. As between riparian use of surface water and overlying use of ground water tributary to the stream, a sharing of the available water supply on the basis of reasonable beneficial use should be made.

Determination of Water Rights

Under provisions of the State Water Code, actions involving determinations of rights to the use of water brought in either state or federal courts may, at the court's discretion, be referred to the State Water Rights Board. Under provisions of Water Code Section 2000, the court may appoint the board to referee "any or all issues involved in the suit," or under Section 2001 it may limit the reference to "investigation of and report upon any or all physical facts involved." This reference procedure may be followed in suits involving either or both surface and ground waters.

A simplified procedure is available for adjudication of rights to the use of water of streams, lakes, and other bodies of water, but the method excludes the determination of rights to

take water from an underground supply other than from a subterranean stream flowing through known and definite channels. Water Code Sections 2500 and 2900, inclusive, authorize the initiation of such a proceeding before the board. The board then makes an engineering investigation and report, holds hearings, and prepares an order of determination which is submitted to the court. After hearings, the court makes a final determination of the water rights.

Court actions which involve a determination of all the relative rights to the use of water of an entire stream or stream system and/or ground water basin afford a basis for distribution of water after decree under watermaster service. Water users may secure the services of the Department of Water Resources under Water Code Sections 4000 to 4407, inclusive, in making distribution of the water to them according to their respective rights, as determined by the court.

Litigation Concerning Water Rights

Shasta River Adjudication

In July 1921, several water users on the lower Shasta River complained to the Division of Water Rights of the lack of water due to diversions by upstream permittees. An investigation was made by the division, and after mutual agreement of the parties, an engineer of the division was stationed in the valley to apportion the water. After receiving a petition for complete adjudication of the water rights on the Shasta River system, an order initiating the proceedings was entered by the division on December 21, 1921.

A field investigation was conducted during the summer months of 1922 and 1923 in which measurements were made of the water supply and the various diversions. The report of this investigation was submitted on July 1, 1925, and the adjudication proceedings were initiated in the Superior Court of the State of California, in and for the County of Siskiyou, in June 1928. The judgment and decree were entered December 30, 1932, in Judgment Book 12, page 189.

Although over 600 diversions are entered in the adjudication, not all of them are reported in this investigation. Some did not meet the minimum size requirements, some have been combined with other diversions, and others have been abandoned.

Shackleford Creek Adjudication

On January 18, 1944, certain water users filed a petition with the Department of Public Works, requesting a determination of the rights of the various claimants in and to the use of the waters of Shackleford Creek and its tributaries. On September 1, 1944, the department began an investigation of water supply, conduits diverting water, lands irrigated, and other data essential to the determination of rights. Field work was completed on about November 1, 1944.

Thirty-seven proofs of rights were filed with the department by claimants, after which the department determined the rights of the parties involved. During the 1945 and 1946 irrigation seasons a trial distribution of waters, supervised by a department watermaster, was conducted.

All the evidence taken by or filed with the department was opened for inspection by all interested parties, and contests of claims were received by the department. Hearings were then held until all contests were disposed by agreement.

An agreement entitled "Stipulation for Order of Determination" was signed by all parties to the determination except two, whose joint claim of right is based upon Application 10350 and Permit 6113. The agreement provides that all of claimants' rights and interests in the use of waters of Shackleford Creek and its tributaries are settled and compromised as set forth in the agreement which was filed October 3, 1949. On January 19, 1950, the Order of Determination was affirmed by the Superior Court of the State of California, in and for the County of Siskiyou, after no exceptions were filed. The decree was entered in Judgment Volume 19, page 472. Application 10350 and Permit 6113 were revoked on February 24, 1959.

John H. Mason, et al, vs. Harry M. Bemrod, et al (French Creek)

On August 3, 1951, owners of riparian lands along French Creek brought suit in the Superior Court of the State of California, in and for the County of Siskiyou, to establish their right against upstream users. An answer and cross complaint were filed on October 17, 1951. On February 25, 1952, an amended cross complaint was filed, naming additional parties who use water from French Creek, and praying that they would appear in court and state the nature and extent of their water right. By order of reference filed March 19, 1953, the Department of Public Works, acting through the State Engineer, was appointed referee to

investigate and determine the issues involved in the action. Upon motion by the Department of Public Works and by "Minute Order" dated February 14, 1955, the court directed that all diverters and potential diverters be brought into the action.

An investigation was conducted by the department which included a survey of the location of ditches and areas irrigated, measurement of streamflow, and water use. The results of these surveys and measurements were compiled and are contained in two reports, "Water Supply and Use of Water on French Creek Stream System, March 19⁵⁴~~45~~," and "Supplemental Report on Water Supply and Use of Water on French Creek Stream System, February 1956." On July 5, 1956, the department, as referee, filed its final report with the court. Exceptions to this report of referee were filed by six water users on French Creek. The Division of Water Resources of the Department of Public Works was succeeded by the State Water Rights Board as referee, effective July 5, 1956.

The case came before the court for hearing and trial between June 16 and June 23, 1958, in which the rights and interests of all parties involved were determined. A judgment was filed July 1, 1958, and entered in Civil Judgments, Volume 7, page 82.

APPENDIX D

DETAILED DESCRIPTIONS OF CERTAIN SURFACE WATER DIVERSIONS

Big Springs Irrigation District (Diversion 43N/5W-3R2, Dwinnell Reservoir Subunit)

The Big Springs Irrigation District was organized March 13, 1913, as the Big Springs Water Company. In the Shasta River Adjudication No. 7035, Siskiyou County Superior Court, December 30, 1932, the district was granted a right to divert 30.0 cubic feet per second from Big Springs from April 1 to October 1 of each year. This right, as described in paragraph 14 of the Judgment and Decree, was based upon water appropriation notice, dated March 22, 1913, and recorded April 2, 1913, in Book of Water Rights, page 55, Siskiyou County Records.

Water is diverted from Big Springs by a 20-inch pump powered by a 250-horsepower electric motor. The intake is 12 feet of 24-inch steel pipe. The discharge is 44-inch wood stave pipe, 1,468 feet in length. The pump, rated at 14,400 gallons per minute, operates under a static head of 58 feet.

The present service area, as shown on sheet 6 of Plate 2, consists of 3,586 acres. Irrigated lands comprise primarily alfalfa and mixed pasture, as shown in Table 7. An additional 64 acres within the boundary of the district were irrigated by diversion 43N/5W-3R1, during 1958.

Edson-Foulke Yreka Ditch Company (Divisions 41N/5W-9P1, Weed Subunit; 41N/5W-6D1, Parks Creek Subunit)

The Edson-Foulke Yreka Ditch Company is successor to the Edson-Foulke Company, the Shasta River Canal Company, the Yreka Water Company, and the Yreka Ditch Company.

In 1854, the Yreka Ditch Company began construction of a ditch to bring water from Shasta River, Parks Creek, and other intermediate streams to the mines in and around the town of Yreka. The main diversion point from Shasta River, 41N/5W-9P1 (Weed Sub-unit), is about 30 air miles southeast of Yreka. However, a survey showed that approximately 95 miles of ditch would have to be built to cover this distance. The undertaking proved to be financially impossible for the backers of the Yreka Ditch Company. The unpaid workers, determined to complete the project, formed the Yreka Water Company, finished the ditch, and delivered water to Yreka Flats in 1856. Through the years, the ditch has been given such names as the "Big Ditch," the "China Ditch," and the "Yreka Ditch." Today it is known as the Edson-Foulke Yreka Ditch Company Ditch, and is the major source of irrigation water in the Gazelle-Grenada area. Diversion facilities on Shasta River consist of a log and rock dam, 2 feet high by 30 feet long, diverting through a concrete diversion box and Parshall flume into the ditch, which is approximately 6 feet in width and 3 feet deep, and flows 4 miles to the Parks Creek diversion. Here the ditch widens to 8 feet and is 4 feet deep for the remaining 8 miles to the point where the water drops down the hillside to the Webb Lateral, which is the primary distribution canal.

In the Shasta River Adjudication Proceedings No. 7035, Siskiyou County Superior Court, December 30, 1932, the following amounts of water were allotted to the Edson-Foulke Yreka Ditch Company.

Paragraph 116 entitles the company to divert from Shasta River at diversion point 41N/5W-9P1 (Weed Subunit), 21.15 cubic feet per second from March 1 to November 1, and 4.55 cubic feet per second from November 1 to March 1. The company can divert, from Parks Creek, 7.45 cubic feet per second, March 1 to November 1, at diversion point 41N/5W-6D1 (Parks Creek Subunit). In addition, 7.45 cubic feet per second and 228 acre-feet storage are allotted to the company from either Shasta River or Parks Creek, or in part from both sources, between November 1 to March 1, via the above-mentioned points of diversion.

Paragraph 117 entitles the company to divert from Shasta River, at diversion point 41N/5W-9P1 (Weed Subunit), 1.75 cubic feet per second from March 1 to November 1, and 0.40 cubic foot per second from November 1 to March 1. The company can divert from Parks Creek, at diversion point 41N/5W-6D1 (Parks Creek Subunit), 0.60 cubic foot per second March 1 to November 1. In addition, 0.60 cubic foot per second is allotted to the company from either Shasta River or Parks Creek, or in part from both sources, between November 1 to March 1 at the above-mentioned points of diversion.

Paragraph 118 entitles the company to divert from Willow Creek, at a point where the Webb Lateral intercepts Willow Creek, 2.10 cubic feet per second from March 1 to November 1, and 0.70 cubic foot per second from November 1 to March 1, in lieu of amounts of water allotted from Shasta River and Parks Creek under Paragraph 117.

Grenada Irrigation District
(Diversión 43N/5W-6D1, Grenada Subunit)

The Grenada Irrigation District was originally organized as the Lucerne Water Company to supply irrigation water to about 4,000 acres located southwest of Grenada. In the Shasta River Adjudication No. 7035, Siskiyou County Superior Court, December 30, 1932, the district was granted a right to divert 40 cubic feet per second from the Shasta River, April 1 to October 1 of each year. This right was based upon Permit No. 501, issued by the Division of Water Rights to the Lucerne Water Company on its Application No. 448, filed August 28, 1916.

The first unit of the pumping plant, having a capacity of 12,500 gallons per minute, was installed and began pumping in April or May 1917. A second pump, rated at 10,000 gallons per minute, was added and started pumping on July 1, 1918.

The district diverts from the river through 1,000 feet of canal used jointly with the Huesman Ditch. A masonry dam is maintained in the river to divert water into the canal, where two 18-inch pumps lift it 72 feet, through 720 feet of 44-inch wood stave pipe to the main canal. It then flows by gravity through 13 miles of unlined earth canal.

The present service area, as shown on sheets 5 and 8 of Plate 2, consists of 1,858 acres, of which 1,322 acres were irrigated during 1958.

Montague Water Conservation District
(Diversión 43N/5W-25L1, Dwinnell Reservoir Subunit)

The Montague Water Conservation District, formerly the Montague Irrigation District, was organized May 5, 1925, after

the dissolution of the Klamath-Shasta Valley Irrigation District. The latter district was organized in 1921 for the purpose of diverting Klamath River water into Shasta Valley. The costs of diverting such water were found to be excessive, and no action was taken to develop the project. The district was dissolved by the Siskiyou County Superior Court on January 23, 1924.

The Montague Irrigation District was then organized, and Shasta River Dam was constructed, forming Dwinnell Reservoir, with an effective storage capacity of about 34,000 acre-feet. The dam is 1,265 feet long by 98 feet high. The capacity was increased in March 1955 to 50,000 acre-feet, after a rubble berm was added to the toe of the dam. Canals were constructed for the purpose of delivering the water to farms in the vicinity of Montague.

In the Shasta River Adjudication No. 7035, Siskiyou County Superior Court, Paragraph 287, December 30, 1932, the district was granted a right to impound 35,000 acre-feet per season in Dwinnell Reservoir, based upon permit 2452, issued by the Division of Water Rights. An additional right to divert 14,000 acre-feet from Parks Creek into the Shasta River above the reservoir was granted in Paragraph 288. This right was based upon Division of Water Rights permit 2453. The gross area of the district was 20,559 acres in 1958 (4,830 acres in Dwinnell Reservoir Subunit, and 15,729 acres in Little Shasta Subunit), of which 7,133 acres were irrigated.

Scott Valley Irrigation District
(Diversions 41N/9W-2B1, Callahan Subunit,
and 43N/9W-3H1, Lower Scott Valley Subunit)

The Scott Valley Irrigation District was organized on July 7, 1917. License No. 441, in the amount of 62.5 cubic feet per second, was issued by the Division of Water Rights in response to Application No. 512, filed by J. A. Matthews, November 2, 1916. The right was assigned to the Scott Valley Irrigation District on October 20, 1917.

Diversion facilities located 3 miles southeast of Etna in Callahan Subunit include a concrete and flashboard dam approximately 2 feet high and 50 feet long, with an earth wing wall. Water is diverted into the main canal and transported along the eastern edge of the valley approximately 16 miles to Fort Jones.

The portion of the district in Lower Scott Valley Subunit is supplied with water by two 12-inch pumps powered by 50-horsepower electric motors located 1 mile west of Fort Jones on the Scott River. Water is pumped through a 24-inch steel pipe, three-quarters of a mile to the lower canal. This canal was previously connected to the main canal by one-half mile of inverted siphon, which was damaged when the highway to Etna was relocated. Permit No. 11768 for 25 cubic feet per second has been issued by the Water Rights Board in response to Application No. 17997, filed by the district on February 11, 1958.

Shasta River Water Users Association
(44N/6W-3N1, Little Shasta Subunit)

The Shasta River Water Users Association is a mutual water company organized in 1912. About 4,000 acres lying north

of Grenada and west of the Shasta River were subdivided on a "land settlement" plan, where the cost of building, implements, stock, etc., was incorporated into the purchase price of the land.

In the Shasta River Adjudication No. 7035, Siskiyou County Superior Court, Paragraph 341, December 30, 1932, the association was granted a right to divert 42 cubic feet per second from the Shasta River, based upon a water appropriation notice dated November 23, 1912, and recorded December 4, 1912, in Book 7 of Water Rights, page 49, Siskiyou County Records.

The pumping plant, located on the west bank of the Shasta River, 3 miles north of Grenada, consists of two units. The High Line Unit is a 12-inch pump rated at 13.95 cubic feet per second with a 225-horsepower electric motor, pumping through 1,970 feet of 24-inch wood stave pipe, discharging into the High Line Canal. The water then flows by gravity north and south, 2-1/2 miles in each direction.

The Low Line Unit is a 16-inch pump rated at 28.1 cubic feet per second with a 360-horsepower electric motor, pumping through 1,703 feet of 36-inch diameter wood stave pipe, discharging into the Low Line Canal. The water then flows by gravity parallel to the High Line Canal, 3-1/2 miles north and 2-3/4 miles south.

The gross area within the boundary, as shown on sheets 2 and 5 of Plate 2, is 6,593 acres (2,199 acres in Grenada Subunit, and 4,394 acres in Little Shasta Subunit), of which 4,259 acres were irrigated in 1958.
